

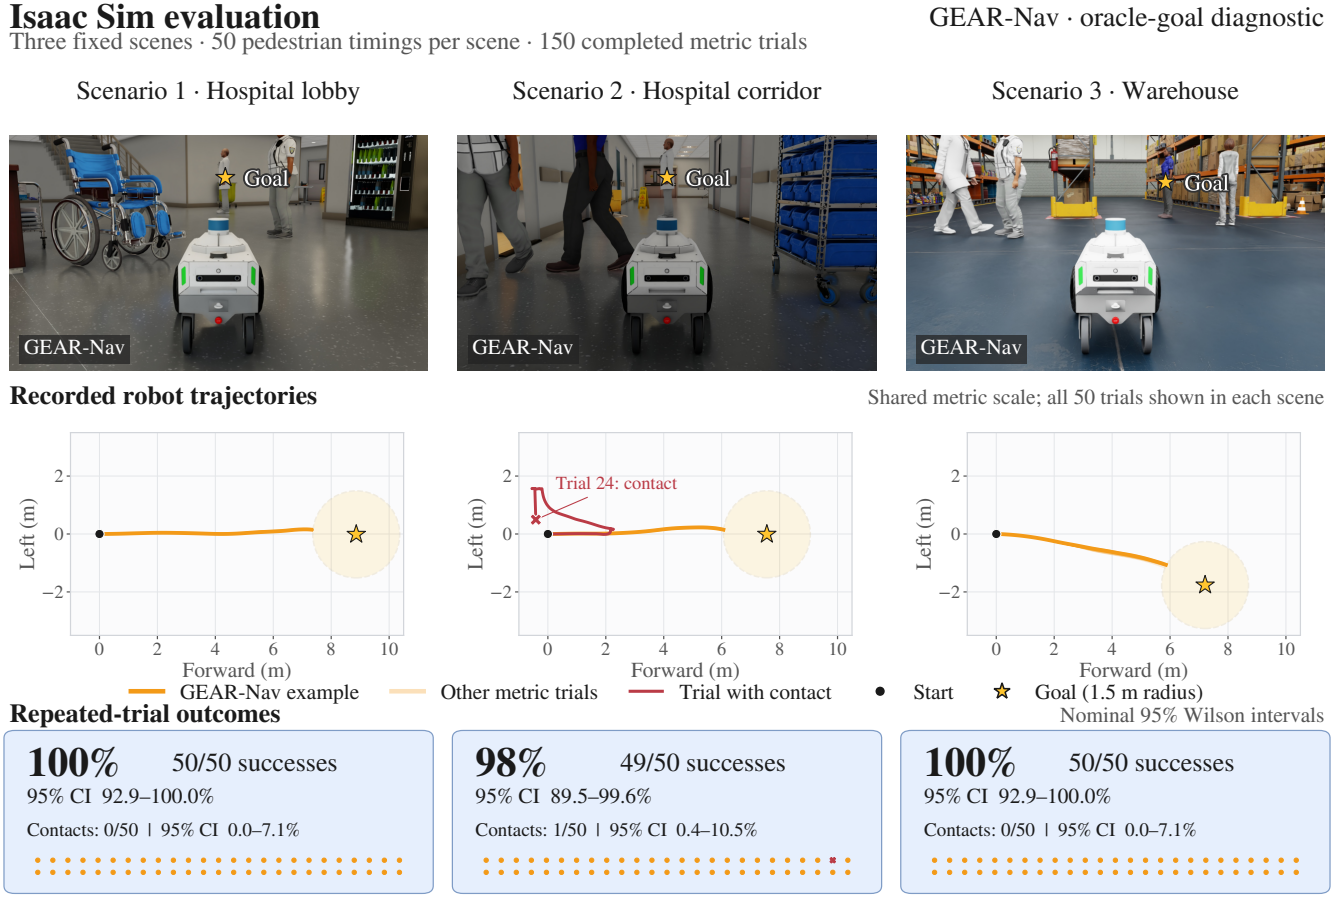

Figure. Isaac Sim evaluation with oracle goals. GEAR-Nav is evaluated over 50 pedestrian timing variants in each of three fixed scenes (150 metric trials). Third-person images show separate collision-free success reruns and are excluded from the metric denominator. The middle row plots all recorded robot trajectories in a fixed local frame for each scene, with a shared metric scale. Bold orange highlights one metric trial; pale orange shows the remaining trials. Red identifies the trial with physical contact; its cross marks the last recorded pose, not the location of contact. Stars and shaded disks denote the goal and its 1.5 m success radius. The lower row reports success and actual-contact counts with nominal 95% Wilson intervals; each dot represents one metric trial. Trials vary pedestrian timing at fixed geometry, and intervals are conditional on this protocol. The policy receives exact simulator goal coordinates transformed into its local frame, so these results are an oracle-goal diagnostic rather than a language-only evaluation. They do not establish statistical significance against another method.
